Overvie	W					

- There are large monthly relative price changes across consumption categories.
- What role do the factors driving those *relative* price changes play in the behavior of inflation in a stable monetary regime?
- Study U.S. from 1995 to 2019, multi-sector NK model.
  - overall contrib'n of relative price shocks to inflation
  - in sample application to inflation shortfall (2012-2019)
  - out of sample application to COVID (maintained assumption regime remained stable)

• Additional discussion of COVID inflation, does it seem to come from same stable regime?

00●00	000	00	000000	0000000	000	00000
Motiva	tion					

- Practical central banking question: to what extent is inflation driven by real shocks when CB is following a stable policy?
- To answer that question we need two things:
  - A model
  - Data from a stable regime
- We have a model, and arguably data from a stable regime.

Intro	Model	Estimates	Properties	Applications	COVID	Conclusion
000●0	000	00	000000	0000000	000	00000
Literati	ure					

- Many, many papers. A few especially relevant:
- Models where distribution of "relative price shocks" matters for inflation:
  - Ball and Mankiw (1995): fixed costs, so firms only adjust if large desired price change
  - Balke and Wynne (2000): sectoral productivity shocks interact with; flexible prices, constant money growth

- Smets et al. (2019): emphasize input-output mechanism
- Reis and Watson (2010) factor model, argue inflation associated to a large extent with relative price changes.

More n	notivatio	on				

- U.S. data 1995-2019
- Monthly inflation (y-axis) closely related to monthly share of relative price increases (x-axis).
- To understand inflation, need to understand distrib'n of relative price changes (*in a stable monetary regime*).

Intro	Model	Estimates	Properties	Applications	COVID	Conclusion
00000	●○○	00	000000	0000000	000	00000
The n	nodel in	one slide				

- Basic NK model, 15 consumption categories ("sectors")
  - Cobb-Douglas across sectors

$$C_t = \prod_j \xi_j^{-\xi_j} c_{j,t}^{\xi_j} \tag{1}$$

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ●の00

• CES within sectors (Dixit-Stiglitz)

$$c_{j,t} = \left(\int \left(c_{l,j,t}\right)^{(\theta-1)/\theta} dl\right)^{\theta/(\theta-1)}, \qquad (2)$$

- Heterogeneity across sectors:
  - Productivity process persistence  $\rho_j$ , shock variance  $\sigma_i^2$
  - Price stickiness parameter (Rotemberg),  $\phi_j$
- Standard Taylor-type rule
- Local analysis around target inflation rate

Intro<br/>00000Model<br/>00Estimates<br/>00Properties<br/>0000000Applications<br/>00000000COVID<br/>0000Conclusion<br/>00000General properties of model (1)

Feasible to perfectly stabilize inflation

- Sectoral productivity shocks (we call them relative price shocks) mean cannot stabilize ALL prices.
- But no problem *in the model* to hit  $\pi^*$  every period: policy rule  $\pi_t = \pi^*$ .
- Intuition from flex price model: real shocks determine relative prices and monetary policy determines inflation.
- With sticky prices, no dichotomy, but monetary policy can still choose inflation (*in the model*).

For a "typical" policy rule, relative price shocks move inflation:

- Sectoral shocks are aggregate shocks, and as such, they move the inflation rate.
- Under a perfect inflation peg  $\pi_t = \pi^*$ , equilibrium function for  $R_t$  involves large responses to all sectoral productivity shocks.

• In contrast, with Taylor type rule, equilibrium  $R_t$  has small responses to all sectoral shocks (*but not zero*).

Intro	Model	Estimates	Properties	Applications	COVID	Conclusion
00000	000	●0	000000	0000000	000	00000
Estimat	tion					

- Maximum likelihood using Kalman filter.
- Observables: sectoral price changes and fed funds rate.
- U.S. data, 1995-January 2020.
- Calibrate parameters that determine steady state.
- Linearize model around steady state with balanced growth:
  - Inflation target  $\pi^* \approx 2\%$ .
  - Sectoral trend prod. growth from trends in relative prices.
  - Accommodate trend in interest rate with time-varying r\*: fit quadratic time trend to r<sub>t</sub>.

## Heterogeneity in price stickiness and shock processes

Category	Price stickiness $\phi_j$	Shock $\sigma_j$
Motor vehicles and parts	7.32	0.46
Furnishings and household durables	0.19	0.39
Recreational goods	0.68	0.38
Other durable goods	0.00	0.58
Food at home	4.23	0.32
Clothing and footwear	0.52	0.55
Gasoline and other energy goods	3.67	6.14
Other nondurable goods	0.03	0.32
Housing and utilities	8.49	0.19
Health care	4.09	0.18
Transportation services	0.26	0.53
Recreation services	2.09	0.24
Food services and accommodations	111.12	1.99
Financial services and insurance	0.00	0.71
Other services	12.89	0.27

- Fits sectoral and aggregate price change data, by construction.
- Sectoral productivity shocks drive own relative prices, small opposite effect on other relative prices (by definition, zero effect on average relative price).
- Sectoral productivity shocks primary driver of inflation  $(\approx 75\%)$ , rest monetary policy (stable regime).
- Model matches empirical relationship between inflation and share of relative price increases.
- Clear heterogeneity in price stickiness, but heterogeneity in shock volatility more important for matching relationship between relative price changes and inflation.

# Intro Model Estimates Properties Applications COVID Conclusion COVID inflation (out of sample)

- Decompose COVID inflation into contrib'ns of various shocks
- Strong caveats!
  - COVID is not in the sample.
  - We filter inflation and price change data under assumption the estimated parameters still apply: inflation anchored at target and only effect of policy is through shocks that are expected to fade.
  - The estimated model has sectoral supply shocks, no sectoral demand shocks.

 COVID inflation (out of sample)

## Intro Model Estimates Properties Applications COVID Conclusion 00000 000 000000 0000000 000000 000000 000000

- Model-based decomposition of COVID inflation can't tell us whether inflation remains anchored.
- Can get *some* insight from recent behavior of inflation and share of relative price increases.
- Recall earlier picture: high inflation corresponded to low share of relative price increases.
- Will provide version of that picture using 208 categories, then add COVID data.
- Recent behavior of inflation seems to represent upward shift relative to prior relationship, but that could represent unusual shocks within same regime.

COVID: Inflation vs. share relative price increases

Intro	Model	Estimates	Properties	Applications	COVID	Conclusion
00000	000	00	000000	0000000	000	•0000
Conclusion						

- Within a stable monetary regime, "relative price shocks" can move around the inflation rate.
- We quantify this effect in an estimated 15-sector NK model; find relative price shocks account for majority of volatility in U.S. monthly inflation, 1995-2019.
- Use the framework to decompose inflation shortfall (in sample) and COVID inflation (out of sample)
- To do list (partial)
  - Add demand shocks (sectoral and aggregate)
  - Allow for lagged cross correlation between sectoral shocks
